12. Phylogenetic Diversity - Communities

Student Name; Z620: Quantitative Biodiversity, Indiana University

07 May, 2021

OVERVIEW

Complementing taxonomic measures of α - and β -diversity with evolutionary information yields insight into a broad range of biodiversity issues including conservation, biogeography, and community assembly. In this worksheet, you will be introduced to some commonly used methods in phylogenetic community ecology.

After completing this assignment you will know how to:

- 1. incorporate an evolutionary perspective into your understanding of community ecology
- 2. quantify and interpret phylogenetic α and β -diversity
- 3. evaluate the contribution of phylogeny to spatial patterns of biodiversity

Directions:

- 1. In the Markdown version of this document in your cloned repo, change "Student Name" on line 3 (above) with your name.
- 2. Complete as much of the worksheet as possible during class.
- 3. Use the handout as a guide; it contains a more complete description of data sets along with examples of proper scripting needed to carry out the exercises.
- 4. Answer questions in the worksheet. Space for your answers is provided in this document and is indicated by the ">" character. If you need a second paragraph be sure to start the first line with ">". You should notice that the answer is highlighted in green by RStudio (color may vary if you changed the editor theme).
- 5. Before you leave the classroom today, it is *imperative* that you **push** this file to your GitHub repo, at whatever stage you are. This will enable you to pull your work onto your own computer.
- 6. When you have completed the worksheet, **Knit** the text and code into a single PDF file by pressing the **Knit** button in the RStudio scripting panel. This will save the PDF output in your '12.PhyloCom' folder.
- 7. After Knitting, please submit the worksheet by making a **push** to your GitHub repo and then create a **pull request** via GitHub. Your pull request should include this file 12.PhyloCom_Worksheet.Rmd and the PDF output of Knitr (12.PhyloCom_Worksheet.pdf).

The completed exercise is due on Monday, May 10th, 2021 before 09:00 AM.

1) SETUP

Typically, the first thing you will do in either an R script or an RMarkdown file is setup your environment. This includes things such as setting the working directory and loading any packages that you will need.

In the R code chunk below, provide the code to:

1. clear your R environment,

```
2. print your current working directory,
3. set your working directory to your /12.PhyloCom folder,
4. load all of the required R packages (be sure to install if needed), and
5. load the required R source file.
rm(list=ls())
getwd()
## [1] "C:/Users/Danny/Desktop/GitHub/QB2021_Peltier-Thompson/2.Worksheets/12.PhyloCom"
setwd("C:/Users/Danny/Desktop/GitHub/QB2021_Peltier-Thompson/2.Worksheets/12.PhyloCom")
package.list <- c('picante', 'ape', 'seqinr', 'vegan', 'fossil', 'reshape', 'simba')</pre>
for (package in package.list) {
  if (!require(package, character.only = TRUE, quietly = TRUE)){
    install.packages(package, repos = 'https://cran.us.r-project.org')
    library(package, character.only = TRUE)
  }
}
## Warning: package 'picante' was built under R version 4.0.5
## Warning: package 'vegan' was built under R version 4.0.5

```

2) DESCRIPTION OF DATA

need to discuss data set from spatial ecology!

In 2013 we sampled > 50 forested ponds in Brown County State Park, Yellowood State Park, and Hoosier National Forest in southern Indiana. In addition to measuring a suite of geographic and environmental variables, we characterized the diversity of bacteria in the ponds using molecular-based approaches. Specifically, we amplified the 16S rRNA gene (i.e., the DNA sequence) and 16S rRNA transcripts (i.e., the RNA transcript of the gene) of bacteria. We used a program called mothur to quality-trim our data set and assign sequences to operational taxonomic units (OTUs), which resulted in a site-by-OTU matrix.

In this module we will focus on taxa that were present (i.e., DNA), but there will be a few steps where we need to parse out the transcript (i.e., RNA) samples. See the handout for a further description of this week's dataset.

3) LOAD THE DATA

- 1. load the environmental data for the Brown County ponds (20130801_PondDataMod.csv),
- 2. load the site-by-species matrix using the read.otu() function,
- 3. subset the data to include only DNA-based identifications of bacteria,
- 4. rename the sites by removing extra characters,
- 5. remove unnecessary OTUs in the site-by-species, and
- 6. load the taxonomic data using the read.tax() function from the source-code file.

```
env <- read.table("data/20130801_PondDataMod.csv", sep = ",", header = TRUE)
env <- na.omit(env)

comm <- read.otu(shared = "./data/INPonds.final.rdp.shared", cutoff = "1")
comm <- comm[grep("*-DNA", rownames(comm)),]
rownames(comm) <- gsub("\\-DNA", "", rownames(comm))
rownames(comm) <- gsub("\\_", "", rownames(comm))

comm <- comm[rownames(comm) %in% env$Sample_ID, ]
comm <- comm[, colSums(comm) >0]

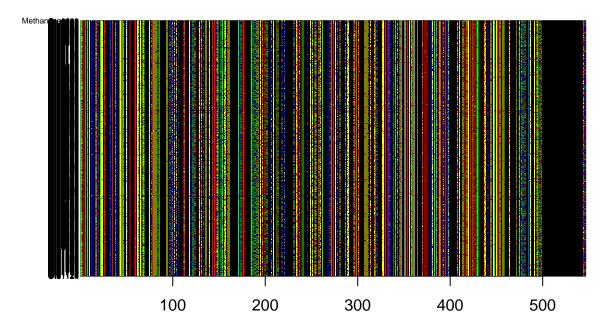

tax <- read.tax(taxonomy = "./data/INPonds.final.rdp.1.cons.taxonomy")</pre>
```

- 1. load the FASTA alignment for the bacterial operational taxonomic units (OTUs),
- 2. rename the OTUs by removing everything before the tab (\t) and after the bar (|),
- 3. import the Methanosarcina outgroup FASTA file,
- 4. convert both FASTA files into the DNAbin format and combine using rbind(),
- 5. visualize the sequence alignment,
- 6. using the alignment (with outgroup), pick a DNA substitution model, and create a phylogenetic distance matrix,
- 7. using the distance matrix above, make a neighbor joining tree,
- 8. remove any tips (OTUs) that are not in the community data set,
- 9. plot the rooted tree.

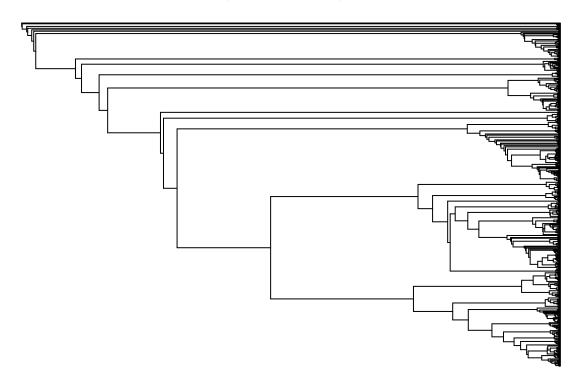

```
ponds.cons <- read.alignment(file = "./data/INPonds.final.rdp.1.rep.fasta", format = "fasta")
ponds.cons$nam <- gsub("\\|.*$", "", gsub("^.*?\t", "", ponds.cons$nam))

outgroup <- read.alignment(file = "./data/methanosarcina.fasta", format = "fasta")
DNAbin <- rbind(as.DNAbin(outgroup), as.DNAbin(ponds.cons))
image.DNAbin(DNAbin, show.labels = T, cex.lab = 0.5, las = 1)</pre>
```

Neighbor Joining Tree

4) PHYLOGENETIC ALPHA DIVERSITY

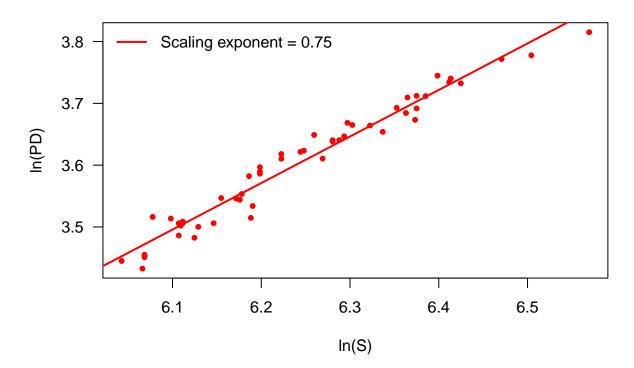

A. Faith's Phylogenetic Diversity (PD)

In the R code chunk below, do the following: 1. calculate Faith's D using the pd() function.

```
pd <- pd(comm, phy, include.root = FALSE)</pre>
```

- 1. plot species richness (S) versus phylogenetic diversity (PD),
- 2. add the trend line, and
- 3. calculate the scaling exponent.

Phylodiversity (PD) vs. Taxonomic Richness (S)

Question 1: Answer the following questions about the PD-S pattern.

a. Based on how PD is calculated, why should this metric be related to taxonmic richness? b. Describe the relationship between taxonomic richness and phylodiversity. c. When would you expect these two estimates of diversity to deviate from one another? d. Interpret the significance of the scaling PD-S scaling exponent.

Answer 1a: because PD is based on community presence absence data and shows how evolutionarily divergent taxa are and the function returns species richness Answer 1b: the greater the PD value, the more evolutionarily divergent your sample is and the greater the taxonomic richness is Answer 1c: if there were a lot of species that were really closely related to eachother Answer 1d: it shows how PD scales with richness, if the value was 1 the richness and PD would increase at the same rate. The value of 0.75 means PD increases slower than richness

i. Randomizations and Null Models

In the R code chunk below, do the following:

 $1. \ estimate the standardized \ effect \ size \ of \ PD \ using \ the \ {\tt richness} \ randomization \ method.$

```
ses.pd <- ses.pd(comm[1:2,], phy, null.model = "richness", runs = 25, include.root = FALSE)
ses.pd2 <- ses.pd(comm[1:2,], phy, null.model = "frequency", runs = 25, include.root = FALSE)
ses.pd3 <- ses.pd(comm[1:2,], phy, null.model = "phylogeny.pool", runs = 25, include.root = FALSE)</pre>
```

Question 2: Using help() and the table above, run the ses.pd() function using two other null models and answer the following questions:

- a. What are the null and alternative hypotheses you are testing via randomization when calculating ses.pd?
- b. How did your choice of null model influence your observed ses.pd values? Explain why this choice affected or did not affect the output.

Answer 2a: I ran "frequency" which randomizes the abundances while maintaining occurance frequency and "phylogeny pool" which randomizes the community by selecting from pool of all species that occured at least once **Answer 2b**: in both the frequency and phylogeny pool run, one pond was more phylogenetically diverse and one was less phylogenetically diverse than the null model but the observed and null model values were more similar in the phylogeny pool model than the frequency model

B. Phylogenetic Dispersion Within a Sample

Another way to assess phylogenetic α -diversity is to look at dispersion within a sample.

i. Phylogenetic Resemblance Matrix

In the R code chunk below, do the following:

1. calculate the phylogenetic resemblance matrix for taxa in the Indiana ponds data set.

```
phydist <- cophenetic.phylo(phy)</pre>
```

ii. Net Relatedness Index (NRI)

In the R code chunk below, do the following:

1. Calculate the NRI for each site in the Indiana ponds data set.

iii. Nearest Taxon Index (NTI)

In the R code chunk below, do the following: 1. Calculate the NTI for each site in the Indiana ponds data set.

Question 3:

- a. In your own words describe what you are doing when you calculate the NRI.
- b. In your own words describe what you are doing when you calculate the NTI.
- c. Interpret the NRI and NTI values you observed for this dataset.
- d. In the NRI and NTI examples above, the arguments "abundance.weighted = FALSE" means that the indices were calculated using presence-absence data. Modify and rerun the code so that NRI and NTI are calculated using abundance data. How does this affect the interpretation of NRI and NTI?

Answer 3a: When you calculate NRI you find how clustered your community is compared to the null model by finding the mean phylogenetic distance of your observed data and the null model. You take the difference between observed and null mean phylogenetic distance and divide that value by the standard deviation of the null model mean phylogenetic distance. Finally you take that value and multiply it by -1. **Answer 3b**: NTI also finds how clustered your community is by using the same formula; however, instead of using the mean phylogenetic distance you would use the nearest phylogenetic neighbor distance which only takes closely related taxa into account **Answer 3c**: the NRI values are all negative and range from \sim -0.3 to \sim -4 which means the community is overdispersed. The NTI values are also predominately negative suggesting overdispersed but there are a few positive values the range being \sim 1 to \sim -2. So the NRI values suggest the community is more overdispersed than the NTI values do **Answer 3d**: taking abundance data into account made both the NRI and NTI interpretations more clustered

5) PHYLOGENETIC BETA DIVERSITY

A. Phylogenetically Based Community Resemblance Matrix

In the R code chunk below, do the following:

- 1. calculate the phylogenetically based community resemblance matrix using Mean Pair Distance, and
- 2. calculate the phylogenetically based community resemblance matrix using UniFrac distance.

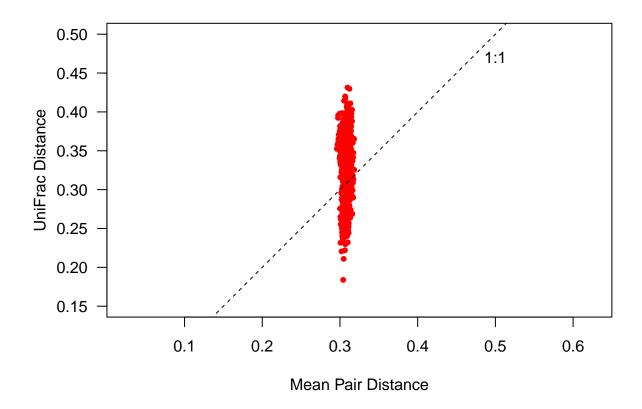

```
dist.mp <- comdist(comm, phydist)</pre>
```

[1] "Dropping taxa from the distance matrix because they are not present in the community data:"
[1] "Methanosarcina"

```
dist.uf <- unifrac(comm, phy)</pre>
```

In the R code chunk below, do the following:

1. plot Mean Pair Distance versus UniFrac distance and compare.

Question 4:

- a. In your own words describe Mean Pair Distance, UniFrac distance, and the difference between them.
- b. Using the plot above, describe the relationship between Mean Pair Distance and UniFrac distance. Note: we are calculating unweighted phylogenetic distances (similar to incidence based measures). That means that we are not taking into account the abundance of each taxon in each site.
- c. Why might MPD show less variation than UniFrac?

Answer 4a: UniFrac is based on how many branch lengths are shared between two taxa while mean pair distance is the average branch length of both taxa. Unifrac measures similarity of branch lengths while mean pair distance measures the similarity of the taxa as a whole Answer 4b: mean pair distance is the average of unifrac distance Answer 4c: mpd is less variable because its an average

B. Visualizing Phylogenetic Beta-Diversity

Now that we have our phylogenetically based community resemblance matrix, we can visualize phylogenetic diversity among samples using the same techniques that we used in the β -diversity module from earlier in the course.

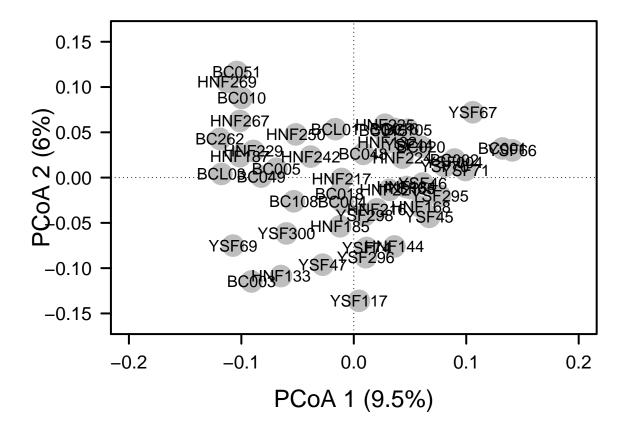

- 1. perform a PCoA based on the UniFrac distances, and
- 2. calculate the explained variation for the first three PCoA axes.

```
pond.pcoa <- cmdscale(dist.uf, eig = T, k = 3)

explainvar1 <- round(pond.pcoa$eig[1] / sum(pond.pcoa$eig), 3) * 100
explainvar2 <- round(pond.pcoa$eig[2] / sum(pond.pcoa$eig), 3) * 100
explainvar3 <- round(pond.pcoa$eig[3] / sum(pond.pcoa$eig), 3) * 100</pre>
```

Now that we have calculated our PCoA, we can plot the results.

- 1. plot the PCoA results using either the R base package or the ggplot package,
- 2. include the appropriate axes,
- 3. add and label the points, and
- 4. customize the plot.

In the following R code chunk: 1. perform another PCoA on taxonomic data using an appropriate measure of dissimilarity, and 2. calculate the explained variation on the first three PCoA axes.

Question 5: Using a combination of visualization tools and percent variation explained, how does the phylogenetically based ordination compare or contrast with the taxonomic ordination? What does this tell you about the importance of phylogenetic information in this system?

Answer 5: it doesn't seem like phylogeny is that important to composition of the system because at most only 9.5% of the variation is explained

C. Hypothesis Testing

i. Categorical Approach

In the R code chunk below, do the following:

1. test the hypothesis that watershed has an effect on the phylogenetic diversity of bacterial communities.

```
watershed <- env$Location
adonis(dist.uf ~ watershed, permutations = 999)

##
## Call:
## adonis(formula = dist.uf ~ watershed, permutations = 999)
##
## Permutation: free</pre>
```

```
##
## Terms added sequentially (first to last)
##
##
             Df SumsOfSqs MeanSqs F.Model
                                               R2 Pr(>F)
                  0.13316 0.066579 1.2679 0.0492 0.028 *
## watershed 2
                  2.57305 0.052511
## Residuals 49
                                           0.9508
## Total
             51
                  2.70621
                                           1.0000
## ---
## Signif. codes: 0 '*** 0.001 '** 0.01 '* 0.05 '.' 0.1 ' 1
adonis(
  vegdist(
   decostand(comm, method = "log"),
   method = "bray") ~ watershed,
 permutations = 999)
##
## Call:
## adonis(formula = vegdist(decostand(comm, method = "log"), method = "bray") ~
                                                                                     watershed, permuta
## Permutation: free
## Number of permutations: 999
##
## Terms added sequentially (first to last)
##
##
             Df SumsOfSqs MeanSqs F.Model

## ---
```

ii. Continuous Approach

Number of permutations: 999

In the R code chunk below, do the following: 1. from the environmental data matrix, subset the variables related to physical and chemical properties of the ponds, and

Signif. codes: 0 '*** 0.001 '** 0.01 '* 0.05 '.' 0.1 ' 1

2. calculate environmental distance between ponds based on the Euclidean distance between sites in the environmental data matrix (after transforming and centering using scale()).

```
envs <- env[, 5:19]
envs <- envs[, -which(names(envs) %in% c("TDS", "Salinity", "Cal_Volume"))]
env.dist <- vegdist(scale(envs), methods = "euclid")</pre>
```

```
## Warning in vegdist(scale(envs), methods = "euclid"): results may be meaningless
## because data have negative entries in method "bray"
```

In the R code chunk below, do the following:

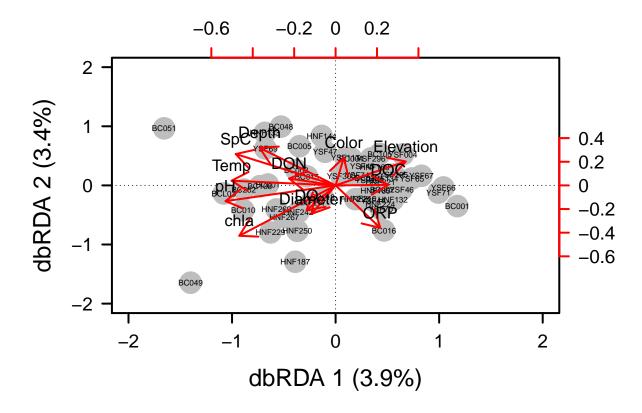

1. conduct a Mantel test to evaluate whether or not UniFrac distance is correlated with environmental variation.

```
##
## Mantel statistic based on Pearson's product-moment correlation
##
## mantel(xdis = dist.uf, ydis = env.dist)
##
## Mantel statistic r: 0.01631
         Significance: 0.286
##
## Upper quantiles of permutations (null model):
##
      90%
             95% 97.5%
                           99%
## 0.0382 0.0469 0.0562 0.0626
## Permutation: free
## Number of permutations: 999
Last, conduct a distance-based Redundancy Analysis (dbRDA).
In the R code chunk below, do the following:
1. conduct a dbRDA to test the hypothesis that environmental variation effects the phylogenetic diversity
of bacterial communities,
2. use a permutation test to determine significance, and 3. plot the dbRDA results
ponds.dbrda <- vegan::dbrda(dist.uf ~ ., data = as.data.frame(scale(envs)))</pre>
anova(ponds.dbrda, by = "axis")
## Permutation test for dbrda under reduced model
## Forward tests for axes
## Permutation: free
## Number of permutations: 999

axis(side = 4, lwd.ticks = 2, cex.axis = 1.2, las = 1, col = "red", lwd = 2.2,
    at = pretty(range(vectors[,2])) * 2, labels = pretty(range(vectors[,2])))
```

Question 6: Based on the multivariate procedures conducted above, describe the phylogenetic patterns of β -diversity for bacterial communities in the Indiana ponds.

Answer 6: Depth, temperature, and chla were the statistically significant variables related to phylogenetic patterns of beta diversity in Indiana ponds. Temp seems like the dbRDA axis 1 and depth and chla were dbRDA axis 2. The statistical significance wasn't incredibly significant though (in the 0.01 range)

6) SPATIAL PHYLOGENETIC COMMUNITY ECOLOGY

A. Phylogenetic Distance-Decay (PDD)

A distance decay (DD) relationship reflects the spatial autocorrelation of community similarity. That is, communities located near one another should be more similar to one another in taxonomic composition than distant communities. (This is analogous to the isolation by distance (IBD) pattern that is commonly found when examining genetic similarity of a populations as a function of space.) Historically, the two most common explanations for the taxonomic DD are that it reflects spatially autocorrelated environmental variables and the influence of dispersal limitation. However, if phylogenetic diversity is also spatially autocorrelated, then evolutionary history may also explain some of the taxonomic DD pattern. Here, we will construct the phylogenetic distance-decay (PDD) relationship

First, calculate distances for geographic data, taxonomic data, and phylogenetic data among all unique pair-wise combinations of ponds.

In the R code chunk below, do the following:

1. calculate the geographic distances among ponds,

- 2. calculate the taxonomic similarity among ponds,
- 3. calculate the phylogenetic similarity among ponds, and
- 4. create a dataframe that includes all of the above information.

```
long.lat <- as.matrix(cbind(env$long, env$lat))
coord.dist <- earth.dist(long.lat, dist = TRUE)

bray.curtis.dist <- 1 - vegdist(comm)
unifrac.dist <- 1 - dist.uf

unifrac.dist.ls <- liste(unifrac.dist, entry = "unifrac")
bray.curtis.dist.ls <- liste(bray.curtis.dist, entry = "bray.curtis")
coord.dist.ls <- liste(coord.dist, entry = "geo.dist")
env.dist.ls <- liste(env.dist, entry = "env.dist")

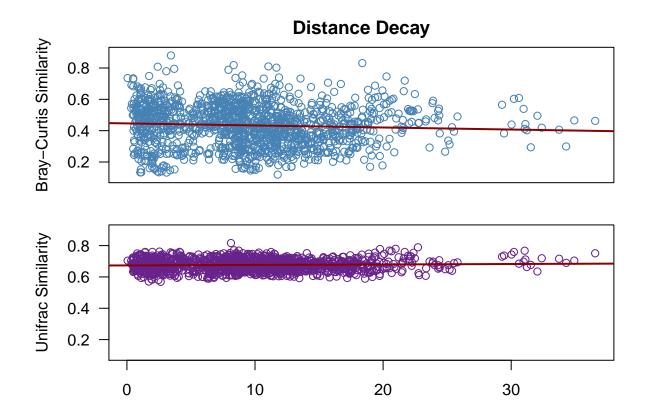

df <- data.frame(coord.dist.ls, bray.curtis.dist.ls[,3], unifrac.dist.ls[,3], env.dist.ls[,3])
names(df)[4:6] <- c("bray.curtis", "unifrac", "env.dist")</pre>
```

Now, let's plot the DD relationships:

- 1. plot the taxonomic distance decay relationship,
- 2. plot the phylogenetic distance decay relationship, and
- 3. add trend lines to each.

```
##
## Call:
## lm(formula = df$bray.curtis ~ df$geo.dist)
## Residuals:
       Min
                 1Q
                      Median
                                   3Q
                                           Max
## -0.31151 -0.08843 0.00315 0.09121 0.43817
##
## Coefficients:
##
                Estimate Std. Error t value Pr(>|t|)
## (Intercept) 0.4463453 0.0066883 66.735
                                              <2e-16 ***
                                              0.0262 *
## df$geo.dist -0.0013051 0.0005864 -2.226
## ---
## Signif. codes: 0 '*** 0.001 '** 0.01 '* 0.05 '.' 0.1 ' 1

## F-statistic: 3.124 on 1 and 1324 DF, p-value: 0.07738
abline(DD.reg.uni , col = "red4", lwd = 2)
```

In the R code chunk below, test if the trend lines in the above distance decay relationships are different from one another.

```
diffslope(df$geo.dist, df$unifrac, df$geo.dist, df$bray.curtis)
```

```
##
## Is difference in slope significant?
## Significance is based on 1000 permutations
##
## Call:
## diffslope(x1 = df$geo.dist, y1 = df$unifrac, x2 = df$geo.dist,
                                                                        y2 = df$bray.curtis)
## Difference in Slope: 0.001603
## Significance: 0.003
##
## Empirical upper confidence limits of r:
##
        90%
                 95%
                        97.5%
## 0.000751 0.000969 0.001121 0.001370
```

Question 7: Interpret the slopes from the taxonomic and phylogenetic DD relationships. If there are differences, hypothesize why this might be.

Answer 7:

SYNTHESIS

Ignoring technical or methodological constraints, discuss how phylogenetic information could be useful in your own research. Specifically, what kinds of phylogenetic data would you need? How could you use it to answer important questions in your field? In your response, feel free to consider not only phylogenetic approaches related to phylogenetic community ecology, but also those we discussed last week in the PhyloTraits module, or any other concepts that we have not covered in this course.
